Natural re-establishment of sagebrush within wildfire-impacted areas is a slow process that can take decades or even centuries. Since 2014, the Douglas Core Area Restoration Team has planted 100,000+ sagebrush seedlings within 5000+ acres of a Sage-grouse Core Population Area of eastern Wyoming. This presentation will highlight the role of collaborative conservation in enhancing habitat for Greater Sage-grouse, along with data-supported lessons the Team has learned through their research investigating environmental constraints to sagebrush growth, survival, and recruitment.

food, beer, and ecological restoration
